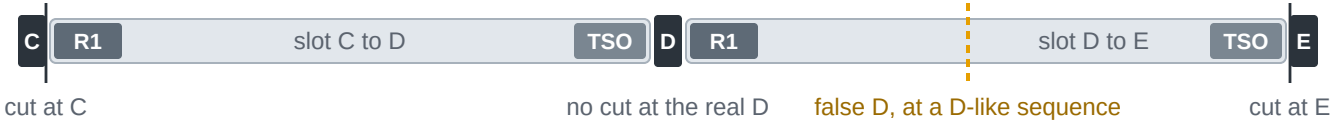
The read with our adapters and primers; vertical lines: where skera cuts



R1: Read1 with the cell label and UMI
TSO: template-switching oligo

The two S-reads skera writes; lima rejects both

lima passes 0.3% of chimeras
and 0.0% of fragments

Our segmentation keeps both molecules

On reads that cover the array's reverse complement (adapters Q to A) the picture is mirrored.
The cut falls in the molecule after the real adapter skera did not cut at, in the direction of the read, and the fragment keeps the Read1 end.
